ASSIGNMENT 4

Name: Aakanksha Bhondve

Grno: 21810939

Rollno: 322004

Comp B1

Aim –

Build a Data model in Python using any classification model (Decision Tree or Naïve Bayes) and infer the result using accuracy score .Compare different classification models (not limited to NB and DT only) with respect to feature selection and accuracy. Infer the result - which model best suit for the dataset chosen.

Theory –

Decision Tree is a Supervised learning technique that can be used for both classification and Regression problems, but mostly it is preferred for solving Classification problems. It is a tree-structured classifier, where internal nodes represent the features of a dataset, branches represent the decision rules and each leaf node represents the outcome.

In a Decision tree, there are two nodes, which are the Decision Node and Leaf Node. Decision nodes are used to make any decision and have multiple branches, whereas Leaf nodes are the output of those decisions and do not contain any further branches.

The decisions or the test are performed on the basis of features of the given dataset.

It is a graphical representation for getting all the possible solutions to a problem/decision based on given conditions.

It is called a decision tree because, similar to a tree, it starts with the root node, which expands on further branches and constructs a tree-like structure.

In order to build a tree, we use the CART algorithm, which stands for Classification and Regression Tree algorithm.

A decision tree simply asks a question, and based on the answer (Yes/No), it further split the tree into subtrees.

Naïve Bayes algorithm is a supervised learning algorithm, which is based on Bayes theorem and used for solving classification problems.

It is mainly used in text classification that includes a high-dimensional training dataset.

Naïve Bayes Classifier is one of the simple and most effective Classification algorithms which helps in building the fast machine learning models that can make quick predictions.

It is a probabilistic classifier, which means it predicts on the basis of the probability of an object.

Some popular examples of Naïve Bayes Algorithm are spam filtration, Sentimental analysis, and classifying articles.

Code and Output –

Classification using Decision Tree

```

Accuracy of Naive Bayes

In [32]:
```
# Accuracy score of the classifer
accuracy_score1= (cm1[0,0]+cm1[1,1])/100
print(accuracy_score1)
```

```
0.9
```

The difference in the accuracy score by 1% is seen, thus Decision Tree is more accurate
